Beard and Mustache Transplant

Facial hair transplantation is a procedure designed to restore hair to the beard and mustache region to thicken the existing hair or to provide hair growth where there is none. The absence of hair could be due to genetics, prior electrolysis or laser hair removal, or even trauma due to surgery, burns or other types of accidents. Some patients seek to have restored a full, thick beard and mustache; others desire a fuller goatee, while others seek to have hair placed into a visible scar.

Eyebrow Hair Transplant:

Transplantation to the eyebrows is a procedure designed to restore growing hair to eyebrows that are overly thin, scarred, or completely missing. The absence of hair can be due to genetics, prior electrolysis or laser hair removal, over plucking, thyroid or other hormonal abnormalities, or trauma due to surgery, burns or other types of accidents. Some patients seek to have restored full, thick eyebrows, others a subtle thickening, while others to have a scar made less visible.
